UNITED STATES DEPARTMENT OF AGRICULTURE
Agricultural Research Administration
Bureau of Entomology and Plant Quarantine
Washington 25, D. C.

December 13, 1944

Results of the trap-scouting performed during the summer of 1944 to secure information on the distribution and possible status of the Japanese beetle in localities outside the area regulated by Federal quarantine are summarized in the attached statement. This includes a list of all localities outside the regulated area where trap-scouting was carried on with positive results during the seasons 1935 to 1944, inclusive, with the respective catches, together with a list of localities where soil treatments have been applied at isolated infestations from 1942 to date. The tabulation on soil treatments includes an estimate of the acreage to be treated as a result of beetles collected during 1944.

Soil treatments completed this fall or assured for the spring of 1945 exceed in acreage those of either of the two preceding years, totaling this year over 1,100 acres. These are undertaken in cooperation with the States or municipalities involved. They are attempts to eradicate outlying incipient infestations or, if eradication is impracticable, to suppress the infestations so that they do not become new centers of spread. This type of treating involves the application of lead arsenate at a dosage of 500 pounds per acre. Treatment is recommended within a radius of 300 feet of all collections of female beetles or multiple finds of either sex. Usually treatment is not applied in sections where solitary male beetles are captured, such areas being reserved for trapping the following season more accurately to determine the conditions of infestation.

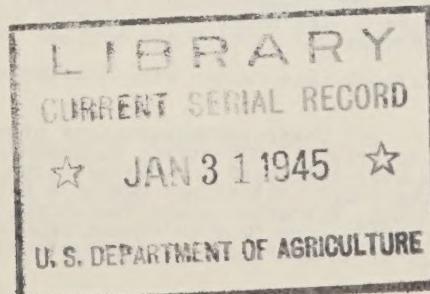

Suppressive measures already applied or assured for the spring of 1945 in localities outside the regulated area, together with State quarantine action in certain outlying areas, will, in most instances, assure protection from spread at least comparable with that afforded if the Federal quarantine were extended. Immediate additions to the area regulated under the Federal Japanese beetle quarantine as a result of the season's trapping records, therefore, will probably be limited to a few election districts in Maryland to include infestations at Flintstone and Hughesville, addition of Ashtabula, Conneaut and Marietta, Ohio as isolated regulated areas, a minor extension of the Toledo, Ohio zone, as well as inclusion of the city of Olean, N. Y. There are a few communities in which soil treating is still under discussion. If not treated they also will be considered for regulation to assure appropriate protection to uninfested States. The North Carolina State Japanese beetle quarantine is being revised to take in the infestation at Blowing Rock and to include spread in several directions from the Asheville area.

The necessity of holding a hearing or conference to consider the extension of the regulated area or modification of the regulations, prior to a revision of the quarantine regulations, can be avoided. It is expected that a revision of the regulations will be issued in the near future.

The accompanying statement is similar to any report on current conditions that might be presented at a public conference. It is issued to make available to State plant quarantine officials and other interested parties the latest information on the distribution and status of the Japanese beetle in areas not now included under Federal quarantine and to acquaint them with the proposed revision of the regulations.

P. N. Annand
Chief of Bureau

REPORT OF RESULTS OF JAPANESE BEETLE TRAPPING
AND CONTROL OPERATIONS DURING 1944

There was a 59 percent expansion in the 1944 trap-scouting program, with 66,828 traps set compared to 41,993 operated in 1943. This was possible due to a resumption of trap manufacture after a number of seasons when materials could not be procured for this purpose. A considerably wider area was surveyed, particularly in Florida, New York and North Carolina. Trapping was again performed in 17 States, but the number of cities trapped was increased to 462, or 301 more than last year.

Beetles were captured in 112 localities. This was the first year beetles had been reported from 36 of these. Sixty-nine of the trap collections were of a few scattered beetles each, while 43 infestations were of such a nature as to warrant soil treatments or quarantine action.

Comprehensive soil treating programs were continued by the States of Georgia, Illinois, Indiana, Michigan, Missouri, New York, North Carolina, Ohio, and Tennessee. This comprised the application of lead arsenate at the rate of 500 pounds per acre within a radius of approximately 300 feet of important beetle finds. A few of the infestations were of such scope that soil treating is impracticable, and quarantine action is contemplated.

Five beetles trapped at Jacksonville, Florida constituted the only captures in the State this season. Seven and one-half acres were treated with arsenate of lead to suppress the insect there.

Soil treatments were applied at the sites of the trap catches of 17 beetles each in Atlanta and Toccoa, Georgia. In each city the treatment covered 1.35 acres. A few beetles collected in Augusta and East Point are not considered of sufficient hazard to require soil treatment there this season.

Negligible collections of a few scattered beetles each were determined in Cicero, East St. Louis, and Highland Park, Illinois. There was an increase in the number of beetles trapped in Chicago, from 257 in 1943 to 708 this season. It is estimated that 275 acres require treatment in Chicago to control the spread as now disclosed. A total of 161.95 acres of this area had been treated up to November 25, with the remaining acreage to be completed later.

Soil treatments have been completed at the Indiana beetle collections at Elkhart, Fort Wayne, Hammond, and Indianapolis. Treating is also planned of the premises at which 7 beetles were caught at Logansport. The only other collections made in the State this year were of a few beetles each at Muncie and Richmond.

Reports of the Maryland State trapping activities indicate that beetles were caught at four localities in non-regulated sections of the State. Quarantine extension to include two of the larger infestations is under consideration.

Soil treatments were applied at the infestations at Detroit, Flint and River Rouge, Michigan. Acreages were 48.3, 8.3 and 32.6, respectively. Treating was omitted this year at Dearborn, where the season's trapping disclosed only two beetles.

A solitary beetle was trapped at the Kansas City, Missouri Airport, for a first-record in that city. Four beetles were also caught in St. Louis. This is an improvement in the St. Louis situation, 14 beetles having been trapped there in 1943. Both of these minor infestations were treated by the State, 1.58 acres at Kansas City and 1.91 acres at St. Louis having received lead arsenate applications.

Trapping in New York resulted in first-record collection of beetles at seven points and disclosure of carry-over beetle populations at 12 other localities. Soil treatments have been completed at Geneva, Newark and Williamson. Treatments are scheduled at Jamestown and Niagara Falls in the spring of 1945. Definite decision has not been made as to whether soil treatment will be undertaken by the municipalities of North Tonawanda and Waterloo. Olean, where 46 beetles were caught, will not be treated but will be taken under regulation.

Trapping in North Carolina resulted in the discovery of beetles in 22 new localities. The insect was also found to have persisted in 17 other communities. Seventeen of the collections in non-quarantined area were of a few beetles each, in sections not requiring soil treatment. Eight are within the area already under State quarantine. Soil treating has been completed in an additional 13 infested centers. The infestation at Blowing Rock has intensified to such an extent that soil treatment with lead arsenate is impracticable and it has been recommended for addition to the State quarantined area. Spread of infestation from the Asheville regulated area requires the adition of two townships to the restricted zone there. Additional applications of spore dust of the type "A" milky disease of the Japanese beetle larva were made in March 1944 to 180 acres in the Asheville area. These were made to control spread of infestation some distance beyond the area treated with spore dust in April 1941.

Except for three first-record beetle collections, two of them of solitary beetles each, the 23 localities in which beetles were trapped in Ohio were known infested centers where practical control work has been performed in previous years. In the State's extensive 1944 soil treating program, applications of lead arsenate have been made at 14 localities. Six of the remaining collection points have so few beetles that treating is not required. An explosive type of spread in Ashtabula, Conneaut, and Marietta has increased the infested areas there to such an extent that soil treatment is not considered feasible. Addition of these three sections to the Federally-regulated area is contemplated.

Two beetle centers in South Carolina, one of two beetles at Florence and the other of 47 beetles at Greenville, were determined this season. The point at which two beetles were trapped will be retrapped next season. Treatment of 15 acres to control the Greenville infestation has been recommended to State officials and is under consideration. Soil treating was performed in Greenville in the spring of 1943, but was omitted following the capture of 20 beetles there in the summer of 1943.

Trapping in Tennessee resulted in the collection of a solitary beetle at Bristol, in which community two beetles were trapped on the Virginia side of the State line, plus an additional six beetles caught at Mountain City, where no previous infestation had been determined. The State applied lead arsenate to 1.75 acres at the latter point.

Positive trapping results in Vermont this season were limited to the first-record collection of a solitary beetle at Richmond.

There was a uniform reduction in all Virginia infestations previously determined outside the regulated area. Positive catches were limited to Bristol, 2 beetles; Harrisonburg, 11; Lynchburg, 5; Warsaw, 2; and Williamsburg, 3. The 11 beetles at Harrisonburg were collected in a single trap situated on a plot that received soil treatment in the spring of 1943. None of the other collections was of a nature to demand immediate soil treatment. Trapping was with negative results in Lexington, Waynesboro, and Woodstock, where soil treatments were applied following the collection of beetles there in 1943. Scouting in Shenandoah indicated the presence of beetles in that town. Exact extent of this infestation will be determined by trapping there next season.
